Introduction & Motivation Markov Decision Process (MDPs) Planning Model Free Reinforcement Learnin

#### WHAT IS REINFORCEMENT LEARNING?

- ➤ Reinforcement learning is the study of how animals and artificial systems can learn to optimize their behavior in the face of rewards and punishments Peter Dyan, Encyclopedia of Cognitive Science
- ► Not supervised learning the animal/agent is not provided with examples of optimal behaviour, it has to be discovered!
- ▶ Not unsupervised learning either we have more guidance than just observations

# LINKS TO OTHER FIELDS

- ▶ It subsumes most artificial intelligence problems
- ▶ Forms the basis of most modern intelligent agent frameworks
- ► Ideas drawn from a wide range of contexts, including psychology (e.g., Skinner's "Operant Conditioning"), philosophy, neuroscience, operations research, Cybernetics

3 / 56

Introduction & Motivation Markov Decision Process (MDPs) Planning Model Free Reinforcement Learning

INTRODUCTION & MOTIVATION MARKOV DECISION PROCESS (MDPs) PLANNING MODEL FREE REINFORCEMENT LEARNING

# Examples of Reinforcement Learning closer to CS

- ► Play backgammon/chess/go/poker/any game (at human or superhuman level)
- ► Helicopter control
- ► Learn how to walk/crawl/swim/cycle
- ► Elevator scheduling
- ▶ Optimising a petroleum refinery
- $\blacktriangleright$  Optimal drug dosage

# THE MARKOV DECISION PROCESS

- ► The primary abstraction we are going to work with is the Markov Decision Process (MDP).
- ► MDPs capture the dynamics of a mini-world/universe/environment
- ▶ An MDP is defined as a tuple  $\langle S, A, T, R, \gamma \rangle$  where:
  - ▶ S,  $s \in S$  is a set of states
  - ▶ A,  $a \in A$  is a set of actions
  - ▶  $R: S \times A$ , R(s, a) is a function that maps state-actions to rewards
  - ▶  $T: S \times S \times A$ , with T(s'|s, a) being the probability of an agent landing from state s to state s' after taking a
  - $\blacktriangleright \ \gamma$  is a discount factor the impact of time on rewards

6 / 50

Introduction & Motivation Markov Decision Process (MDPs) Planning Model Free Reinforcement Learning

#### INTRODUCTION & MOTIVATION MARKOV DECISION PROCESS (MDPS) PLANNING MODEL FREE REINFORCEMENT LEARNIN

#### THE MARKOV PROPERTY AND STATES

#### ► States represent sufficient statistics.

- ► Markov Property ensures that we only care about the present in order to act we can safely ignore past states
- ► Think Tetris all information can be captured by a single screen-shot

# AGENTS, ACTIONS AND TRANSITIONS

- ► An agent is an entity capable of actions
- ► An MDP can capture any environment that is inhabited either by
  - ► Exactly one agent
  - ▶ Multiple agents, but only one is adaptive
- ► Notice how actions are part of the MDP notice also how the MDP is a "world model"
- ▶ The agent is just a "brain in a vat"
- ▶ The agent perceives states/rewards and outputs actions
- ► Transitions specify the effects of actions in the world (e.g., in Tetris, you push a button, the block spins)

7/56

TRODUCTION & MOTIVATION MARKOV DECISION PROCESS (MDPs) PLANNING MODEL FREE REINFORCEMENT LEARN

#### ITRODUCTION & MOTIVATION MARKOV DECISION PROCESS (MDPS) PLANNING MODEL FREE REINFORCEMENT LEARNING

#### REWARDS AND THE DISCOUNT FACTOR

- $\blacktriangleright$  Rewards describe state preferences
- Agent is happier in some states of the MDP (e.g., in Tetris when the block level is low, a fish in water, pacman with a high score)
- ► Punishment is just low/negative reward (e.g., being eaten in pacman)
- $\triangleright$   $\gamma$ , the discount factor,
  - ► Describes the impact of time on rewards
  - $\blacktriangleright$  "I want it now", the lower  $\gamma$  is the less important future rewards are
- ▶ There are no "springs/wells of rewards" in the real world
  - ► What is "human nature"?

#### Examples of Reward Schemes

- ► Scoring in most video games
- ▶ The distance a robot walked for a bipedal robot
- ▶ The amount of food an animal eats
- ▶ Money in modern societies
- ► Army Medals ("Gamification")
- $\blacktriangleright$  Vehicle routing
  - ightharpoonup (-Fuel spent on a flight)
  - ightharpoonup (+ Distance Covered)
- ► Cold/Hot
- Do you think there is an almost universal reward in modern societies?

9 / 5

INTRODUCTION & MOTIVATION MARKOV DECISION PROCESS (MDPs) PLANNING MODEL FREE REINFORCEMENT LEARNING

INTRODUCTION & MOTIVATION MARKOV DECISION PROCESS (MDPs) PLANNING MODEL FREE REINFORCEMENT LEARNING

#### Long Term Thinking

- ightharpoonup It might be better to delay satisfaction
- ► Immediate reward is not always the maximum reward
- ► In some settings there are no immediate rewards at all (e.g., most solitaire games)
- ▶ MDPs and RL capture this
- "Not going out tonight, study"
- $\blacktriangleright$  Long term investment

#### Policy

- ► The MDP (the world) is populated by an agent (an actor)
- ▶ You can take actions (e.g., move around, move blocks)
- ightharpoonup The type of actions you take under a state is called the policy
- ▶  $\pi: S \times A, \pi(s, a) = P(a|s)$ , a probabilistic mapping between states and actions
- $\blacktriangleright$  Finding an optimal policy is mostly what the RL problem is all about

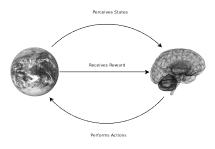

11/56

INTRODUCTION & MOTIVATION MARKOV DECISION PROCESS (MDPS) PLANNING MODEL FREE REINFORCEMENT LEARNIN

#### INTRODUCTION & MOTIVATION MARKOV DECISION PROCESS (MDPs) PLANNING MODEL FREE REINFORCEMENT LEARNING

# THE FULL LOOP

- ▶ See how the universe described by the MDP defines actions, not just states and transitions
- ▶ An agent needs to act upon what it perceives
- ▶ Notice the lack of body "brain in a vat". Body is assumed to be part of the world.

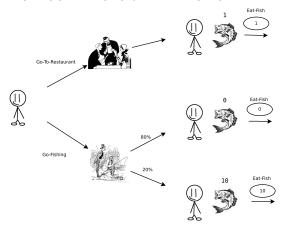

# FISHING TOON

- ► Assume a non-player character (let's call her toon)
- ► Toon is Hungry!
- ► Eating food is rewarding
- ▶ Has to choose between going fishing or going to the restaurant (to eat fish)
  - ▶ Fishing can get you better quality of fish (more reward), but you might also get no fish at all (no reward)!
  - ▶ Going to the restaurant is a low-risk, low-reward alternative

MARKOV DECISION PROCESS (MDPs) PLANNING MO

# FISHING TOON: PICTORIAL DEPICTION

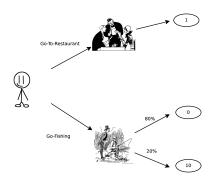

# EXPECTED REWARD

- ▶ Our toon has to choose between two different actions
- ► Go-To-Restaurant or Go-Fishing
- ▶ We assume that toon is interested in maximising the expected sum of happiness/reward
- ▶ We can help the toon reason using the tree backwards

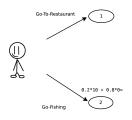

Introduction & Motivation Markov Decision Process (MDPs) Planning Model Free Rein

Introduction & Motivation Markov Decision Process (MDPs) Planning Model Free Reinforcement Lear

# Reasoning Backwards (1)

# Reasoning Backwards (2)

INTRODUCTION & MOTIVATION MARKOV DECISION PROCESS (MDPs) PLANNING MODEL FREE REINFORCEMENT LEARNING

# CORRECT ACTION

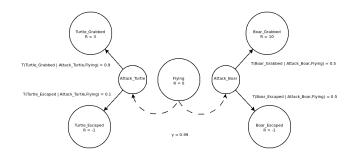

- ► Toon should go Go-Fishing
- Would you do the same?
- ► Would a pessimist toon do the same?
- ▶ We just went through the following equation:

$$Q^*(s, a) = R(s, a) + \gamma \sum_{s' \in S} T(s'|s, a) \max_{a' \in A} Q^*(s', a')$$

- ▶ Looks intimidating but it's really simple
- ▶ Let's have a look at another example
  - ▶ How about toon goes to the restaurant after failing to fish?
  - ▶ How would that change the reward structure?

INTRODUCTION & MOTIVATION MARKOV DECISION PROCESS (MDPs) PLANNING MODEL FREE REINFORCEMENT LEARN

# EXAMPLE MDP - EAGLEWORLD

# Agent Goals

- ► The agent's goal is to maximise its long term reward  $\mathbb{E}_{\pi} \left[ \sum_{t=0}^{\infty} \gamma^{t} R\left(s^{t}, a^{t}\right) \right]$
- ▶ Risk Neutral Agent think of the EagleWorld example
- ▶ Rewards can be anything, but most organisms receive rewards only in a very limited amount of states (e.g., fish in water)
- ▶ What if your reward signal is only money?
  - ► Sociopathic, egotistic, greed-is-good Gordon Gekko (Wall Street, 1987)
  - ▶ No concept of "externalities" agents might wreak havoc for marginal reward gains
  - ▶ Same applies to all "compulsive agents" think Chess

# Searching for a good Policy

- ▶ One can possibly search through all combinations of policies until she finds the best
- ► Slow, does not work in larger MDPs
- ► Exploration/Exploitation dilemma
  - ► How much time/effort should be spend exploring for solutions?
  - ▶ How much time should be spend exploiting good solutions?

Introduction & Motivation Markov Decision Process (MDPs) Planning Model Free Rei

Introduction & Motivation Markov Decision Process (MDPs) Planning Model Free Reinforcement Learn

#### PLANNING

- ► Who was doing the thinking in the previous example (You? The eagle?)
- ► An agent has access to model, i.e., has a copy of the MDP (the outside world) in its mind
- ▶ Using that copy, it tries to "think" what is the best route of
- ▶ It then executes this policy on the real world MDP
- ► You can't really copy the world inside your head, but you can copy the dynamics
- ▶ "This and that will happen if I push the chair"
- ► Thinking, introspection...
- ▶ If the model is learned, sometimes it's called "Model Based RL"

# Bellman Expectation Equations / Bellman BACKUPS

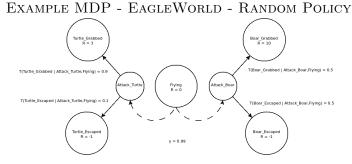

- ▶ The two most important equations related to MDP
- ► Recursive definitions
- $\begin{array}{l} \blacktriangleright \quad V^\pi(s) = \sum\limits_{a \in A} \pi(s,a) \left( R(s,a) + \gamma \sum\limits_{s' \in S} T(s'|s,a) \, V^\pi(s') \right) \\ \blacktriangleright \quad Q^\pi(s,a) = R(s,a) + \gamma \sum\limits_{s' \in S} T(s'|s,a) \sum\limits_{a' \in A} \pi(s',a') \, Q^\pi(s',a') \end{array}$
- ► Called V-Value(s) (state-value function) and Q-Value(s) (state-action value function) respectively
- ▶ Both calculate the expected rewards under a certain policy

INTRODUCTION & MOTIVATION MARKOV DECISION PROCESS (MDPs) PLANNING MODEL FREE REINFORCEMENT LEARNING

# Link between $V^{\pi}$ and $Q^{\pi}$

- ightharpoonup V and Q are interrelated
- ►  $V^{\pi}(s) = \sum_{a \in A} \pi(s, a) Q^{\pi}(s, a)$ ►  $Q^{\pi}(s, a) = R(s, a) + \sum_{s' \in S} T(s'|s, a) V^{\pi}(s')$

# Introduction & Motivation Markov Decision Process (MDPs) Planning Model Free Reinforcement Learning

$$\begin{array}{l} \pi(Flying, Attack\_Boar) = 0.5, \pi(Flying, Attack\_Turtle) = 0.5 \\ Q(Flying, Attack\_Boar) = 0.99*(10*0.5+0.5*-1) = 4.455 \\ Q(Flying, Attack\_Turtle) = 0.99*(0.9*3+0.1*-1) = 2.574 \\ V^{\pi}(Flying) = \\ 0.5, Q^{\pi}(Flying, Attack\_Turtle) + 0.5, Q(Flying, Attack\_Boar) = 3.5145 \end{array}$$

Introduction & Motivation Markov Decision Process (MDPs) Planning Model Free Re

CTION & MOTIVATION MARKOV DECISION PROCESS (MDPs) PLANNING MODEL FR.

# OPTIMAL POLICY AND THE BELLMAN OPTIMALITY EQUATION

- ▶ An optimal policy can be defined in terms of Q-values
- $\blacktriangleright$  It is the policy that maximises Q values

- ► It is the policy that maximises Q values

  ►  $V^*(s) = \max_{a \in A} R(s, a) + \gamma \sum_{s' \in S} T(s'|s, a) V^*(s')$ ►  $Q^*(s, a) = R(s, a) + \gamma \sum_{s' \in S} T(s'|s, a) \max_{a' \in A} Q^*(s', a')$ ►  $\pi^*(s, a) = \begin{cases} 1 & \text{if } a = \arg\max_{a \in A} Q^*(s, a) \\ 0 & \text{otherwise} \end{cases}$

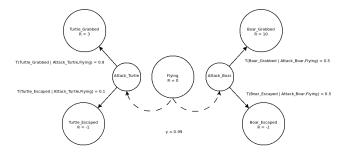

# Link between $V^*$ and $Q^*$

- ► Again, they are interrelated
- $\begin{array}{ll} \blacktriangleright & V(s)^* = \max_{a \in A} \, Q^*(s,a) \\ \blacktriangleright & Q^*(s,a) = R(s,a) + \gamma \sum\limits_{s' \in S} T(s'|s,a) \, V^*(s') \end{array}$

Introduction & Motivation Markov Decision Process (MDPs) Planning Model Free Reinforce

Introduction & Motivation Markov Decision Process (MDPs) Planning Model Free Reinforcement Lear

#### EXAMPLE MDP - EAGLEWORLD - OPTIMAL POLICY

 $Q(Flying, Attack\_Boar) = 0.99*(10*0.5+0.5*-1) = 4.455$  $Q(Flying, Attack\_Turtle) = 0.99*(0.9*3 + 0.1*-1) = 2.574$  $\pi^*(\mathit{Flying}, \mathit{Attack\_Boar}) = 1, \, \pi^*(\mathit{Flying}, \mathit{Attack\_Turtle}) = 0$  $V^*(Flying) = Q(Flying, Attack Boar) = 4.455$ 

Agents Revisited

- ► An Agent can be composed of a number of things
- ► A policy
- ► A Q-Value/and or V-Value Function
- ► A Model of the environment (the MDP)
- ► Inference/Learning Mechanisms
- ► An agent has to be able to *create a policy* either on the fly or using Q-Values
- ► The Model/Q/V-Values serve as intermediate points towards constructing a policy

#### SIMPLIFYING ASSUMPTIONS

#### ► Assume deterministic transitions

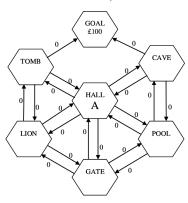

- ► Thus, taking an action on a state will lead only to ONE other possible state for some action  $a_c$ 
  - $$\begin{split} & \blacktriangleright \ T(s'|s,a_i) = \left\{ \begin{array}{l} 1 \quad \text{if } a_i = a_c \\ 0 \quad \text{otherwise} \end{array} \right. \\ & \blacktriangleright \ V^*(s) = \max_{a \in A} \left[ R(s,a) + \gamma \, V^*(s') \right] \\ & \blacktriangleright \ Q(s,a) = R(s,a) + \gamma \max_{a' \in A} Q(s',a') \end{split}$$
- $\blacktriangleright$  It is easier now to solve for problems that have loops in them
- ▶ We can also attempt to learn Q-Values without a model!
- ▶ All we need in order to find the optimal policy is Q(s, a)

# DETERMINISTIC Q-LEARNING (1)

- ▶ The policy is deterministic from start to finish
- ▶ We will use  $\pi(s) = \arg \max Q(s, a)$  to denote the optimal policy
- ► The algorithm now is:
  - ▶ Initialise all Q(s, a) to low values
  - ► Repeat:
    - ightharpoonup Select an action a using an exploration policy
  - ► Also known as "Dynamic Programming", "Value Iteration"

#### An Example (1)

(From Paul Scott's ML lecture notes)

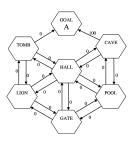

R(HALL, To - CAVE) = 0

# An Example (2)

Next suppose the agent, now in state CAVE , selects action To - GOAL

R(CAVE, To - GOAL) = 100, Q(GOAL, a) = 0 for all actions (there are no actions)

Hence  $Q(CAVE, To - GOAL) = 100 + \gamma * 0 = 100$ 

INTRODUCTION & MOTIVATION MARKOV DECISION PROCESS (MDPs) PLANNING MODEL FREE REINFORCEMENT LEARNING

#### Introduction & Motivation Markov Decision Process (MDPs) Planning Model Free Reinforcement Learning

#### An Example (3)

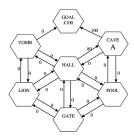

Let's start at hall again and select the same action To-CAVE

$$R(\mathit{HALL},\mathit{To-CAVE}) = 0,\; Q(\mathit{CAVE},\mathit{GOAL}) = 100$$

Q(CAVE, a) = 0 for all other actions a

Hence 
$$\max_{a \in A} Q(CAVE, a) = 100$$
, if  $\gamma = 0.8$ ,

$$Q(HALL, To - CAVE) = 0 + \gamma * 100 = 80$$

# EXPLORATION / EXPLOITATION

- ▶ How do we best explore?
- ▶ Choose actions at random but this can be very slow
- $\bullet$   $\epsilon$  greedy is the most common method
- ▶ Act ϵ-greedily

$$\star \pi^{\epsilon}(s, a) = \begin{cases} a = \arg \max_{a \in A} Q(s, a) & \text{if } 1 - \epsilon + \epsilon/|A| \\ U_a & \text{otherwise} \end{cases}$$

- $\epsilon$ -greedy means acting greedily with probability  $1 \epsilon$ , random
- ▶ When you are done, act greedily  $\pi(s) = \arg \max Q(s, a)$

# Algorithms for non-deterministic settings

- ▶ What can we do if the MDP is not deterministic?
- ► Q-learning

• 
$$Qs, a) \leftarrow Q(s, a) + \eta \left[ R(s, a) + \gamma \max_{a' \in A} Q(s', a') - Q(s, a) \right]$$

- - $\qquad \qquad \bullet \quad Q(s,a) \leftarrow Q(s,a) + \eta \left[ R(s,a) + \gamma Q(s',a') Q(s,a) \right]$
- ► SARSA(1)/MC,

  - $\begin{array}{l} \blacktriangleright \ Q(s,a) \leftarrow Q(s,a) + \eta \left[\mathbf{v}_{\tau} Q(s,a)\right] \\ \blacktriangleright \ \mathbf{v}_{\tau} \leftarrow R(s,a) + \gamma R(s',a') + ... \gamma^2 R(s'',a'') + \gamma^{\tau-1} R(s^{\tau},a^{\tau}) \end{array}$
- $\bullet$   $\eta$  is a small learning rate, e.g.,  $\eta = 0.001$

# SARSA VS Q-LEARNING VS MC

- ▶ MC: updated using the whole chain
  - ▶ Possibly works better when the markov property is violated
- ► SARSA: update based on the next action you actually took
  - ► On Policy learning
- ▶ Q-Learning: update based on the best possible next action
  - $\blacktriangleright$  Will learn optimal policy even if acting off-policy

# Monte Carlo Control (1)

- ► Remember Q is just a mean/average
- ► MC (Naive Version)
  - ▶ Start at any state, initialise  $Q_0(s, a)$  as you visit states/actions
- ▶ Add all reward you have seen so far to  $\mathbf{v}_{\tau}^{\mathbf{i}} = R(s',a') + \gamma R(s'',a'') + \gamma^2 R(s''',a''') + \gamma^{\tau-1} R(s^{\tau},a^{\tau}) \text{ for }$
- $Q_n(s,a) = E_{\pi^{\epsilon}}[\mathbf{v}_{\tau}^i] = \frac{1}{n} \sum_{i=1}^n \mathbf{v}_{\tau}^i$ , where n is the times a state is

# Monte Carlo Control (2)

- $\epsilon$ -greedy means acting greedily  $1 \epsilon$ , random otherwise
- ▶ Better to calculate mean incrementaly

$$\begin{split} Q_n(s,a) &= E_{\pi_n}[\mathbf{v}_{\tau}^{\mathbf{i}}] \\ Q_n(s,a) &= \frac{1}{n} \sum_{i=1}^n \mathbf{v}_{\tau}^{\mathbf{i}} \\ Q_n(s,a) &= \frac{1}{n} \left( \mathbf{v}_{\mathbf{t}}^{\mathbf{t}} + \mathbf{v}_{\tau}^2 .... \mathbf{v}_{\tau}^{\mathbf{n}-1} + \mathbf{v}_{\tau}^{\mathbf{n}} \right) \\ Q_n(s,a) &= \frac{1}{n} \left( \sum_{i=1}^{n-1} \mathbf{v}_{\tau}^{\mathbf{i}} + \mathbf{v}_{\tau}^{\mathbf{n}} \right) \end{split}$$

Introduction & Motivation Markov Decision Process (MDPs) Planning Model Free Reinforcement Learning

INTRODUCTION & MOTIVATION MARKOV DECISION PROCESS (MDPs) PLANNING MODEL FREE REINFORCEMENT LEARNING

#### Monte Carlo Control (3)

by definition

$$Q_{n-1}(s,a) = \frac{1}{n-1} \sum_{i=1}^{n-1} \mathbf{v}_{\tau}^{i} \implies (n-1) Q_{n-1}(s,a) = \sum_{i=1}^{n-1} \mathbf{v}_{\tau}^{i}$$

$$Q_n(s, a) = \frac{1}{n} ((n-1)Q_{n-1}(s, a) + \mathbf{v}_{\tau}^{\mathbf{n}})$$

$$Q_n(s, a) = \frac{1}{n} (Q_{n-1}(s, a)n - Q_{n-1}(s, a) + \mathbf{v}_{\tau}^{\mathbf{n}})$$

$$Q_n(s, a) = \frac{Q_{n-1}(s, a)n}{n} + \frac{-Q_{n-1}(s, a) + \mathbf{v}_{\tau}^{\mathbf{n}}}{n}$$

$$Q_{n}(s,a) = \frac{Q_{n-1}(s,a)n}{n} + \frac{-Q_{n-1}(s,a) + \mathbf{v}_{\tau}^{n}}{n}$$

$$Q_{n}(s,a) = Q_{n-1}(s,a) + \frac{\mathbf{v}_{\tau}^{n} - Q_{n-1}(s,a)}{n}$$

# Monte Carlo Control (4)

▶ But  $\pi^n$  changes continuously, so the distribution of rewards is non-stationary

$$\begin{split} Q_n(s,a) &= Q_{n-1}(s,a) + \frac{1}{n} \left[ \mathbf{v}_{\tau}^{\mathbf{n}} - Q_{n-1}(s,a) \right] \to \text{Bandit case} \\ Q_n(s,a) &= Q_{n-1}(s,a) + \eta \left[ \mathbf{v}_{\tau}^{\mathbf{n}} - Q_{n-1}(s,a) \right] \to \text{Full MDP case} \end{split}$$

► A Bandit can be seen as MDP with a chain of length one (i.e. s) - like the initial EagleWorld,  $\eta$  is a learning rate (e.g., 0.001)

# Monte Carlo Control (5)

- ▶ Start at any state, initialise  $Q_0(s, a)$  as you visit states/actions
- ▶ Act  $\epsilon$ -greedily
- $\blacktriangleright$  Wait until episode ends, i.e. a terminal state is hit  $\epsilon$  set to some low value, e.g., 0.1
- ▶ Add all reward you have seen so far to  $\mathbf{v}_{\tau}^{i} = R(s, a) + \gamma R(s', a') + ... \gamma^{2} R(s'', a'') + \gamma^{\tau - 1} R(s^{\tau}, a^{\tau})$  for episode i
- $Q_n(s, a) = Q_{n-1}(s, a) + \eta \left[ v_{\tau}^n Q_{n-1}(s, a) \right]$

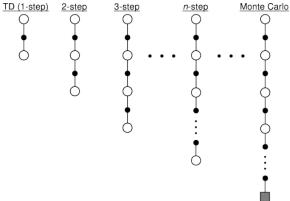

# FROM MONTE CARLO CONTROL TO SARDA AND Q-Learning

- ▶ With MC we update using the rewards from the whole chain
- ► Can we update incrementally?

$$\begin{split} Q_{n}(s,a) &= Q_{n-1}(s,a) + \eta \left[ \mathbf{v}_{\tau}^{n} - Q_{n-1}(s,a) \right] \\ Q_{n}(s,a) &= Q_{n-1}(s,a) + \eta \left[ R(s,a) + \gamma R(s',a') + \ldots \gamma^{2} R(s'',a'') + \gamma^{\tau-1} R(s^{\tau},a^{\tau}) - Q_{n-1}(s,a) \right] \\ Q_{n}(s,a) &= Q_{n-1}(s,a) + \eta \left[ R(s,a) + \gamma (R(s',a') + \ldots \gamma R(s'',a'') + \gamma^{\tau-2} R(s^{\tau},a^{\tau})) - Q_{n-1}(s,a) \right] \\ Q_{n}(s,a) &= Q_{n-1}(s,a) + \eta \left[ R(s,a) + \gamma (\mathbf{v}_{\tau}^{n,(s',a')}) - Q_{n-1}(s,a) \right] \\ Q_{n}(s,a) &= Q_{n-1}(s,a) + \eta \left[ R(s,a) + \gamma Q_{n-1}(s',a') - Q_{n-1}(s,a) \right] \end{split}$$

Let's go over the toon example, without a
